**Answer:** Processing a high dimensional data on a limited memory machine is a strenuous task, your interviewer would be fully aware of that. Following are the methods you can use to tackle such situation:

1. Since we have lower RAM, we should close all other applications in our machine, including the web browser, so that most of the memory can be put to use.
2. We can randomly sample the data set. This means, we can create a smaller data set, let's say, having 1000 variables and 300000 rows and do the computations.
3. To reduce dimensionality, we can separate the numerical and

Q2: Is rotation necessary in PCA? If yes, Why? What will

happen if you don't rotate the components?

**Answer:** Yes, rotation (orthogonal) is necessary because it maximizes the difference between variance captured by the component. This makes the components easier to interpret. Not to forget, that's the motive of doing PCA where, we aim to select fewer components (than features) which can explain the maximum variance in the data set. By doing rotation, the relative location of the components doesn't change, it only changes the actual coordinates of the points.

**Answer:** If you have worked on enough data sets, you should deduce that cancer detection results in imbalanced data. In an imbalanced data set, accuracy should not be used as a measure of performance because 96% (as given) might only be predicting majority class correctly, but our class of interest is minority class (4%) which is the people who actually got diagnosed with cancer. Hence, in order to evaluate model performance, we should use Sensitivity (True Positive Rate), Specificity (True Negative Rate), F measure to determine class wise performance of the classifier. If the minority class performance is found to be poor, we can undertake the

**Answer:** Prior probability is nothing but, the proportion of dependent (binary) variable in the data set. It is the closest guess you can make about a class, without any further information. For example: In a data set, the dependent variable is binary (1 and 0). The proportion of 1 (spam) is 70% and 0 (not spam) is 30%. Hence, we can estimate that there are 70% chances that any new email would be classified as spam.

Likelihood is the probability of classifying a given observation as 1 in presence of some other variable. For example: The

which involves helping a food delivery company save more money. The problem is, company's delivery team aren't able to deliver food on time.

As a result, their customers get unhappy. And, to keep them happy, they end up delivering food for free. Which machine learning algorithm can save them?

three things:

(<https://corporate.analyticsvidhya.com/career/>)

**Answer:** Low bias occurs when the model's predicted values are near to actual values. In other words, the model becomes

(<https://www.analyticsvidhya.com/campus-ambassador/>)

models using a single learning algorithm. Later, the model predictions are combined using voting (classification) or averaging (regression).

Also, to combat high variance, we can:

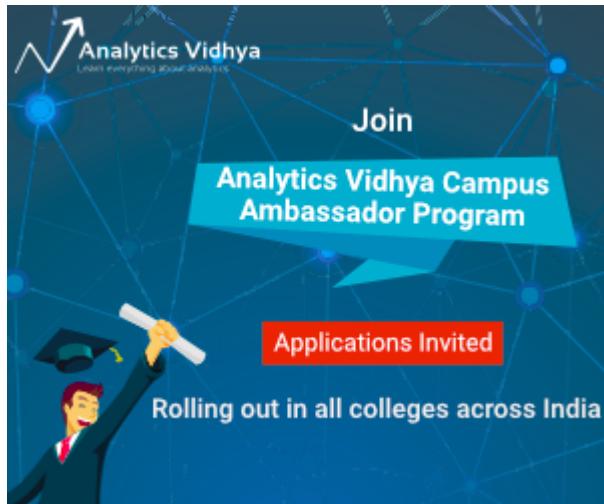

1. Use regularization technique, where higher model coefficients get penalized, hence lowering model complexity.
2. Use top n features from variable importance chart. May be, with all the variable in the data set, the algorithm is having difficulty in finding the meaningful signal.

**Q10. You are given a data set. The data set contains many variables, some of which are highly correlated and you know about it. Your manager has asked you to run PCA. Would you remove correlated variables? Why?**

a data set, of which 2 are correlated variables have a higher variance than it would

exhibit with uncorrelated variables. Also, adding correlated variables lets PCA put more importance on those variable,

you are now anxious to result, you build 5 GBM algorithm would do the magic.

should perform better than decided to combine those models are known to return high accuracy, but you are unfortunate. Where did you miss?

([https://www.analyticsvidhya.com/campus-ambassador/?utm\\_source=AVblog\\_sidebottom](https://www.analyticsvidhya.com/campus-ambassador/?utm_source=AVblog_sidebottom))

**Answer:** As we know, ensemble learners are based on the idea of combining weak learners to create strong learners. But, these learners provide superior result when the combined models are uncorrelated. Since, we have used 5 GBM models and got no accuracy improvement, suggests that the models are correlated. The problem with correlated models is, all the models provide same information.

For example: If model 1 has classified User1122 as 1, there are high chances model 2 and model 3 would have done the same, even if its actual value is 0. Therefore, ensemble learners are

built on the premise of combining weak uncorrelated models to obtain better predictions. [HOME](https://www.analyticsvidhya.com) ([HTTPS://WWW.ANALYTICSVIDHYA.COM](https://www.analyticsvidhya.com)) LEARN ✓ ENGAGE ✓ COMPETE ✓

([https://www.analyticsvidhya.com/corporate/?utm\\_source=banner5yearanniversary](https://www.analyticsvidhya.com/corporate/?utm_source=banner5yearanniversary))

our manager has informed me about removing from multicollinearity. What is the true? Without losing any information, build a better model?

We can create a correlation matrix between variables having correlation above 0.8 (or higher). In addition, we can use Variance Inflation Factor (VIF) (https://www.analyticsvidhya.com/campus-ambassador/?utm\_source=Avblog\_sidebottom) to check the presence of multicollinearity. VIF value  $\leq 4$  suggests no multicollinearity whereas a value of  $\geq 10$  implies serious multicollinearity. Also, we can use tolerance as an indicator of multicollinearity.

But, removing correlated variables might lead to loss of information. In order to retain those variables, we can use penalized regression models like ridge or lasso regression. Also, we can add some random noise in correlated variable so that the variables become different from each other. But, adding noise might affect the prediction accuracy, hence this approach should be carefully used.

**Q17. Rise in global average temperature led to decrease in number of pirates around the world. Does that mean that decrease in number of pirates caused the climate change?**

**Answer:** After reading this question, you should have understood that this is a classic case of "causation and correlation". No, we can't conclude that decrease in number of pirates caused the climate change because there might be other factors (lurking or confounding variables) influencing this phenomenon.

Therefore, there might be a correlation between global average temperature and number of pirates, but based off this information we can't say that pirates died because of rise in global average temperature.

## **Q19. What is the difference between covariance and correlation?**

**Answer:** Correlation is the standardized form of covariance.

Covariances are difficult to compare. For example: if we calculate the covariances of salary (\$) and age (years), we'll get different covariances which can't be compared because of having unequal scales. To combat such situation, we calculate correlation to get a value between -1 and 1, irrespective of their respective scale.

**Q23. You've built a random forest model with 10000 trees.**

**You got delighted after getting training error as 0.00. But, the validation error is 34.23. What is going on? Haven't you trained your model perfectly?**

**Answer:** The model has overfitted. Training error 0.00 means the classifier has mimiced the training data patterns to an extent, that they are not available in the unseen data. Hence, when this classifier was run on unseen sample, it couldn't find those patterns and returned prediction with higher error. In random forest, it happens when we use larger number of trees

than necessary. Hence, to avoid these situation, we should tune

number of trees. Using cross validation.

**Q30. What do you understand by Type I vs Type II error ?**

**Answer:** Type I error is committed when the null hypothesis is

true and we reject it, also known as a 'False Positive'. Type II error is committed when the null hypothesis is false and we accept it, also known as 'False Negative'.

**Q32. You have been asked to evaluate a regression model based on R<sup>2</sup>, adjusted R<sup>2</sup> and tolerance. What will be your criteria?**

**Answer:** Tolerance (1 / VIF) is used as an indicator of multicollinearity. It is an indicator of percent of variance in a predictor which cannot be accounted by other predictors. Large values of tolerance is desirable.

We will consider adjusted R<sup>2</sup> as opposed to R<sup>2</sup> to evaluate model fit because R<sup>2</sup> increases irrespective of improvement in prediction accuracy as we add more variables. But, adjusted R<sup>2</sup> would only increase if an additional variable improves the

accuracy of model, otherwise stays same. It is difficult to commit a gene mutation threshold value for adjusted R<sup>2</sup> because it varies between data sets. For example: a gene mutation data set might result in lower adjusted R<sup>2</sup> and still provide fairly GET HIRED to a stock market data

It calculates distance horizontally or vertically only. It has dimension restrictions. On the other hand, euclidean metric can

distance. Since, the data on, euclidean distance is a

the movement made by a manhattan distance because it is a sum of all movements.

**Answer:** It's simple. It's just like how babies learn to walk. Every time they fall down, they learn (unconsciously) & realize that their legs should be straight and not in a bend position. The next time they fall down, they feel pain. They cry. But, they learn 'not to stand like that again'. In order to avoid that pain, they try harder. To succeed, they even seek support from the door or wall or anything near them, which helps them stand firm.

This is how a machine works & develops intuition from its environment.

Note: The interview is only trying to test if have the ability of explain Analytics Vidhya concepts in simple terms.

**Q36. Considering the long list of machine learning algorithm, given a data set, how do you decide which one to use?**

**Answer:** You should say, the choice of machine learning algorithm solely depends of the type of data. If you are given a data set which is exhibits linearity, then linear regression would be the best algorithm to use. If you given to work on images, audios, then neural network would help you to build a robust model.

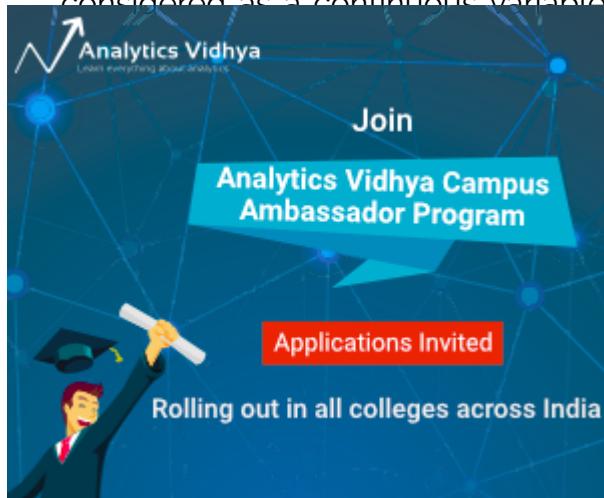

If the data comprises of non linear interactions, then a boosting

or bagging algorithm should be the choice. If the business requires analytics to build a model which can be deployed, then we'll use regression or a decision tree model (easy to interpret and explain) instead of black-box algorithms like SVM, GBM etc.

(<https://www.analyticsvidhya.com/corporate/>)

**Answer:** For better predictions, categorical variable can be considered as a continuous variable only when the variable is

necessary when the model technique introduces a cost with the objective function.

Hi Chibole,  
 It's always a good thing to establish yourself as an expert in a specific field. This helps the recruiter to understand that you are a detailed oriented person. In machine learning, thinking of building your expertise in supervised learning would be good, but companies want more than that. Considering, the variety of data these days, they want someone who can deal with unlabeled data also. In short, they look for someone who isn't just an expert in operating Sniper Gun, but can use other weapons also if needed.

 Dear Kunal,

Few queries i have regarding AIC

- 1)why we multiply -2 to the AIC equation
- 2)where this equation has been built.

Rgds

I have a small suggestion on Dimensionality Reduction, We can also use the below mentioned techniques to reduce the dimension of the data.

### 1. Missing Values Ratio

Data columns with too many missing values are unlikely to carry much useful information. Thus data columns with number of missing values greater than a given threshold can be removed. The higher the threshold, the more aggressive the reduction.

### 2. Low Variance Filter

Similarly to the previous technique, data columns with little changes in the data carry little information. Thus all data columns with variance lower than a given threshold

are removed. A word of caution: variance is range dependent therefore normalization is required before applying this technique. (<https://www.analyticsvidhya.com>)

**GET HIRED** ▾

2. High Correlation Filter

similar trends are also likely to occur in other columns. Therefore, one can use correlation coefficient between columns to identify which columns are highly correlated. If the correlation coefficient between two nominal columns is more than 0.8, then one of them can be removed. The correlation coefficient between two continuous variables is calculated by dividing the covariance of the two variables by the product of their standard deviations. The Pearson's correlation coefficient is used for this purpose. The correlation coefficient ranges from -1 to 1. A value of 1 indicates a perfect positive linear relationship, while a value of -1 indicates a perfect negative linear relationship. A value of 0 indicates no linear relationship. Correlation does not measure causation; it only measures association. Correlation does not measure causation; it only measures association. Correlation does not measure causation; it only measures association.

4. Random Forests / Ensemble Trees

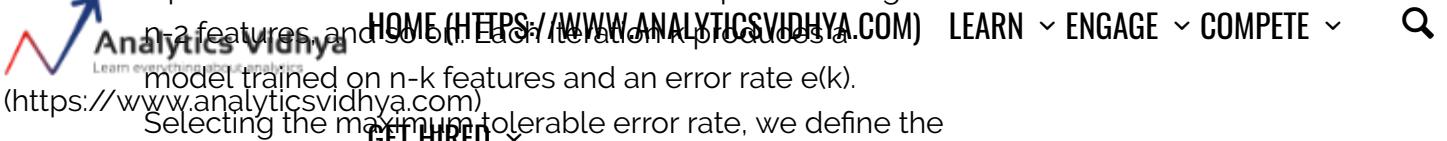

Random forests are a type of ensemble learning algorithm that uses multiple decision trees to make predictions. Each tree in the forest is trained on a different subset of the data, and the final prediction is made by averaging the predictions of all the trees. This approach is referred to as random selection in addition to bagging. The basic idea is to generate a large number of trees against a target attribute's usage statistics to select a set of features. Specifically, a random forest (RF) consists of 2000 (or more) of very shallow trees being trained on a small fraction of the input attributes. If an attribute is often selected as the best split point, it is most likely an informative ambassador. Feature selection is based on the attribute usage statistics in the random forest tells us – relative to the other attributes – which are the most predictive attributes.

## 5. Backward Feature Elimination

In this technique, at a given iteration, the selected classification algorithm is trained on n input features. Then we remove one input feature at a time and train the same model on n-1 input features n times. The input feature whose removal has produced the smallest increase in the error rate is removed, leaving us with n-1

input features. The classification is then repeated using

n-2 features, and so on. Each iteration produces a

model trained on n-k features and an error rate e(k).

Selecting the maximum tolerable error rate, we define the

**GET HIRED**

smallest number of features necessary to reach that

error rate. This is done with the selected machine

Really awesome article thanks. Given the influence young, budding students of machine learning will likely have in the future, your article is of great value.
